Figure B1.12 Photographs of the Ruamahanga River at Various Flows

Ruamahanga River at Te Ore Ore Bridge, 24 November 2005, approximately half median flow ($7 \text{ m}^3/\text{s}$)

Ruamahanga River at Wardells Bridge, 24 November 2005, approximately half median flow ($7 \text{ m}^3/\text{s}$)

Ruamahanga River at The Cliffs, 24 November 2005, approximately half median flow ($7 \text{ m}^3/\text{s}$)

Ruamahanga River at Te Ore Ore Bridge, 20 December 2005, approximately median flow ($11 \text{ m}^3/\text{s}$)

Ruamahanga River at Wardells Bridge, 20 December 2005, approximately median flow ($11 \text{ m}^3/\text{s}$)

Ruamahanga River at The Cliffs, 20 December 2005, approximately median flow ($11 \text{ m}^3/\text{s}$)

Ruamahanga River at Te Ore Ore Bridge 5 December 2005, river in flood
(90 m³/s)

Ruamahanga River at Wardells Bridge, 5 December 2005, river in flood (90 m³/s)

Ruamahanga River at The Cliffs, 5 December 2005, river in flood (90 m³/s)

Appendix B2 Groundwater Information

Figure B2.1 Locations of wells, test pits and bore holes at and in the vicinity of the Masterton WWTP site.

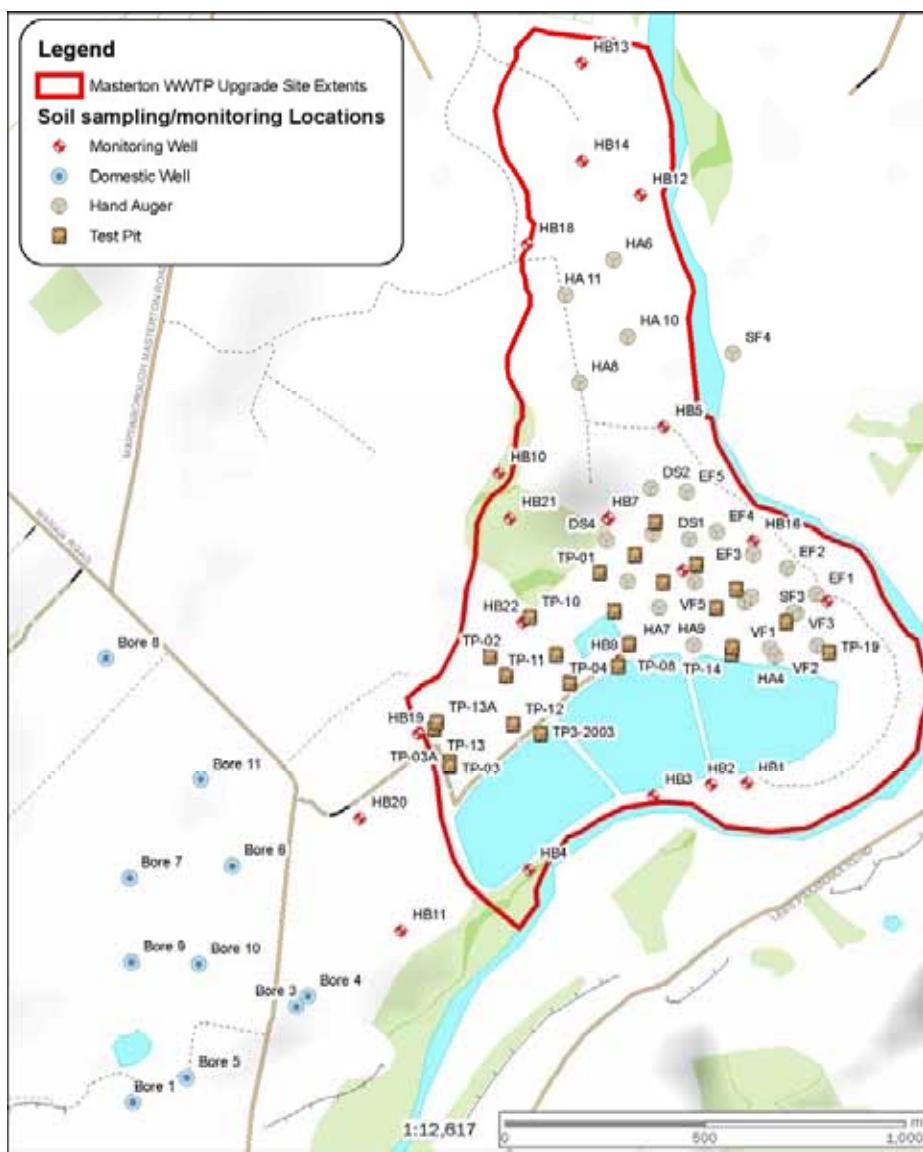

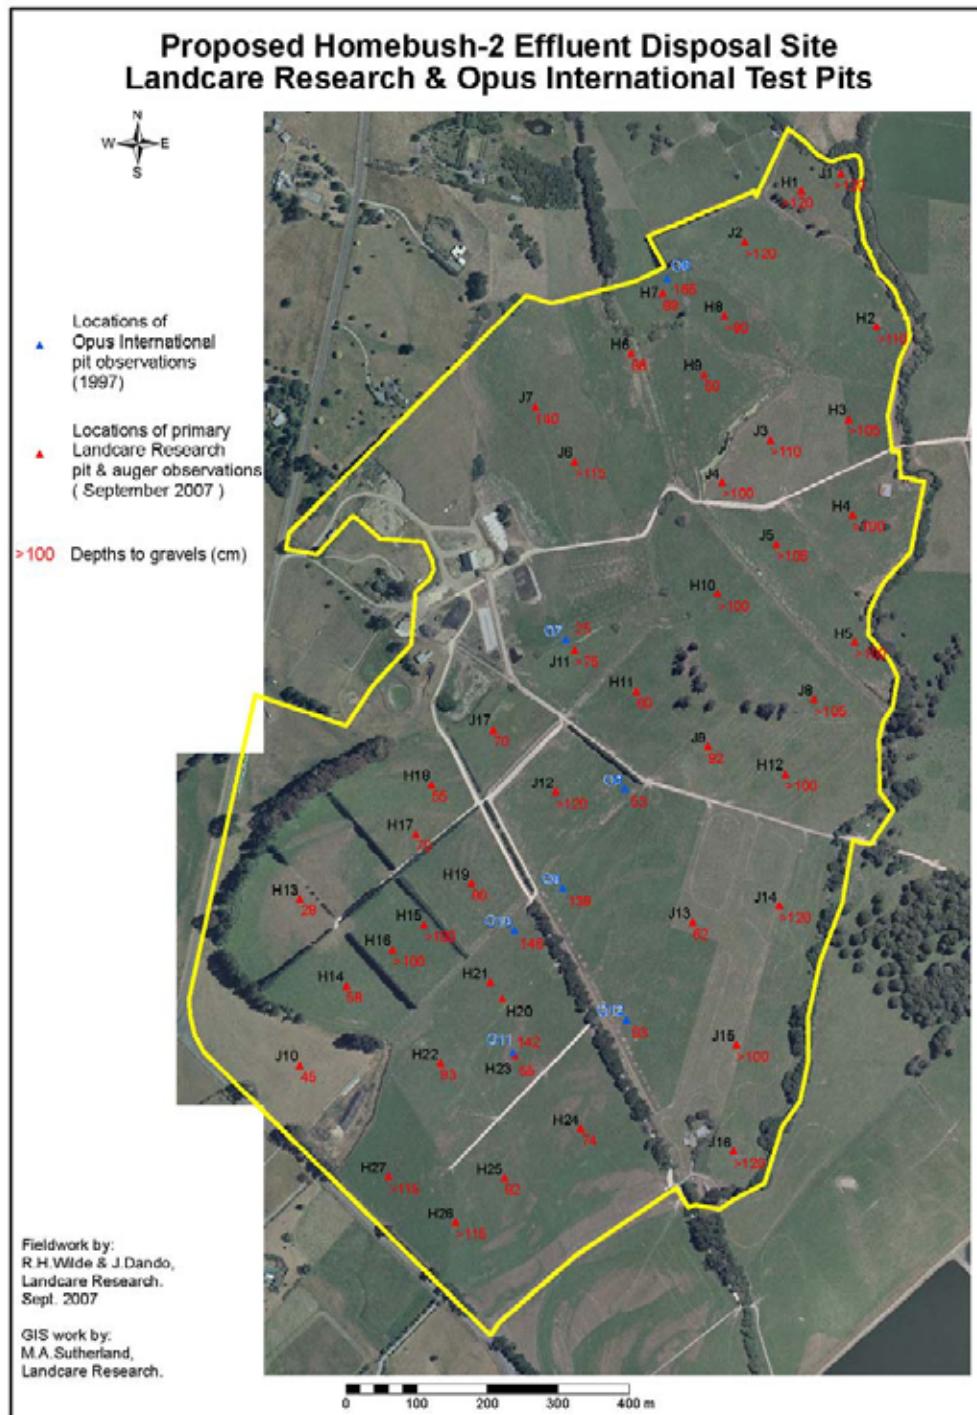

Figure B2.2 Landcare Research & Opus International Test Pits

Appendix B3 Surface Water Quality Guidelines

Physico-chemical, macroinvertebrate and microbiological guidelines for Receiving Water Quality

Variable (units)	Guideline Value	Guideline type	Reference
Water clarity (m)	1.6, 20% change for Class A waters where clarity is an important characteristic	Aesthetic	MfE (1994)
Water colour – Hue (Munsell points)	10 ^a (for Class A waters)	Aesthetic	MfE (1994)
Livestock drinking – nutrients (N, g/m ³)	90 for nitrate; 9 for nitrite	Livestock health	ANZECC (2000)
Livestock drinking – microbial toxins (microcystins, µg/L)	2.3	Livestock health	ANZECC (2000)
Aquatic life – total ammonia-nitrogen (N, g/m ³)	1.61 @ pH 7.5	Ecological protection	ANZECC (2000) ^b
Aquatic life – nitrate-nitrogen (N, g/m ³)	7.2	Ecological protection	ANZECC (2000) ^c
Macroinvertebrate (species and macroinvertebrate community index (MCI) and semi-quantitative index (SQMCI))	Descriptors with assessment relative to upstream site	Ecological protection	Stark (1998)
Periphyton taxonomic and biomass (Species richness)	Descriptors with assessment relative to upstream site	Ecological protection	-
Temperature change (°C)	3	Ecological protection	WRFP A8.2(2)
pH range	6.5 – 9.0	Ecological protection	ANZECC (1992)
Dissolved oxygen (%saturation)	≥80	Ecological protection	RMA 1991 Third schedule
Periphyton cover – aesthetics/recreation (%cover); biomass (Chlorophyll a; mg/m ²)	>60% mat cover >30% filamentous cover 120 Chlorophyll	Aesthetic (nuisance growths)	MfE (2000)
Periphyton cover: nutrients – recreation (DRP, mg/m ³)	30	Aesthetic (nuisance growths)	MfE (2000) ^d
Bathing water quality – microbiological (<i>E. coli</i> , cfu/100mL)	130 'Surveillance mode' 260 'Alert mode' 550 'Action mode'	Human health	MfE (2003)
Drinking water quality – microbial toxins (microcystins, µg/L; cells/mL)	1.0 20,000	Human health	WHO (1998)

^a A 5 Munsell point change is recommended for Class A waters where hue is an important characteristic of the water body (MfE 1994, p35), with a 10 point change for other waters. The optically shallow Ruamahanga River is dominated by bed colour and a 10 point change is considered appropriate.

^b Guideline for a "slightly-moderately disturbed" ecosystem for a 95% level of protection (ANZECC 2000, Table 8.3.7)

^c Value recalculated from ANZECC (2000) Table 3.4.1; see correction:
<http://www.mfe.govt.nz/publications/water/anzecc-water-quality-guide-02/anzecc-nitrate-correction-sep02.html>

^d Site-specific guideline value for low-flow discharges (NIWA 2003x)

1 Purpose

This Land Treatment Management Plan sets out the management practices required for the sustainable operation and maintenance of the land treatment system involving irrigation of treated effluent from the proposed new Masterton Wastewater Land Treatment Plant.

The purpose of this Plan is to minimise the risk to public health and environmental damage through the provision of operational guidelines for border strip irrigation of pond effluent.

This Plan is provided as supporting information to the *Masterton Wastewater Treatment Plant and Disposal System Long-Term Upgrade, Resource Consent Applications and Assessment of Effects on the Environment*. The Plan will be a 'living document' and will therefore be updated as needed to incorporate requirements of the resource consent conditions and details of the scheme following its detailed design, construction and commissioning.

This Plan shall be implemented in conjunction with the following plans;

- *Masterton Wastewater Treatment Plant at Homebush – Mitigation Plan*, which deals with the operation of the treatment plant
- *Odour, Aerosols and Noise Monitoring Plan* which deals with monitoring of the oxidation ponds and dealing with potential complaints. This plan was required by the 2003 interim resource consent conditions.
- *Masterton Wastewater Treatment Plant at Homebush – Risk Communication Strategy* which presents a strategy for public communication regarding the discharge to the Ruamahanga River and public health issues associated with that

All of the above plans will be incorporated into the one document when the new scheme is completed.

2 Description of the System

The proposed new treatment plant will comprise of two parallel primary oxidation ponds and five maturation ponds in-series. The ponds will either discharge treated effluent to the Ruamahanga River or to the land treatment scheme, or both simultaneously depending on the river/land conditions at the time. During river flows below half median or median (refer to Section 3) effluent will not be discharged to the river and will therefore be irrigated to land with the balance going to storage. The oxidation ponds provide a minimum storage volume of 275,000 m³. At times when irrigation is not possible due to excess soil moisture or rainfall, effluent will go to storage and/or to the river depending on river flow conditions. The land treatment scheme is the preferred means of discharge and should be used in preference to a discharge to the river or storage of effluent.

Effluent will be pumped from the final maturation pond to the land treatment scheme. The "Proposed Land Treatment" scheme (refer Drawing C-601, C-603 & C-604) will be developed as the initial scheme while the "Potential Future Land Treatment" area may be developed in the future depending on funding constraints.

The Proposed Land Treatment (referred to in this Plan as the land treatment scheme) is to be developed on two sites owned by MDC; the 91 ha site and the east portion of the 107 ha site (gross site areas). The land treatment scheme initially will have a net area for irrigation of 75 ha. The 75 ha area has been split up into 14 zones and covers the area between the Makoura Stream and the river stopbank, the river berm area, and the area on the east side of the 107 ha site.

In the two to three years following commissioning of the new ponds, the existing oxidation pond area will be converted to border strip irrigation. The area available provides an additional 22 ha i.e. a total of 97 ha of irrigation area.

The land treatment scheme will be planted in pasture for baleage or silage production.

3 River Discharge

Effluent will be discharged from pond storage to the Ruamahanga River whenever storage exceeds the minimum operating levels in the ponds and river flow conditions permit. Discharges to the river will be controlled automatically by the plant control system. A predictive model will be used "to overview" the discharge operation, to give more certainty that the exceedance of the river flow trigger will be sustained for a sufficient duration. This will avoid discharging when the river flow exceeds the trigger value for durations of less than about six hours. The Mt Bruce flow recorder will provide six to nine hours advance warning of the magnitude of a fresh. This flow data will be used by the automatic control system to initiate a discharge when the trigger at Wardell's Bridge is exceeded and there is a strong likelihood that the fresh will be sustained for more than six hours. A "start to discharge" delay of 15 to 30 minutes will ensure that the river flow has comfortably exceeded the trigger value, thus overcoming any minor errors in the flow measurement data.

The discharge to the Ruamahanga River shall be operated in accordance with the following river trigger conditions and the requirements of the resource consent conditions for the scheme;

- Summer (1 Nov to 30 April); discharge to river at greater than median flow ($12.3 \text{ m}^3/\text{s}$)
- Winter (1 May to 31 Oct); discharge to river at greater than half median river flows ($6.15 \text{ m}^3/\text{s}$)
- Discharge to be maintained at a river flow:effluent ratio of 30:1
- Maximum discharge rate to be 1,200 litres/s
- No discharge above river flows greater than $300 \text{ m}^3/\text{s}$.

Note that prior to the development of the existing oxidation pond area into land treatment, total discharge volumes to land may be less depending on rainfall and therefore in order to not exceed the available storage volume, the river discharge trigger has been set accordingly;

- Summer and winter periods; discharge to river at greater than median river flows ($12.3 \text{ m}^3/\text{s}$)
- All other rules as above.

4 Effluent Quality

The effluent quality from the oxidation ponds is suitable for discharge to the Ruamahanga River and irrigation to land. The expected effluent quality from the Masterton oxidation ponds is set out in Table 4.1.

Table 4.1

Effluent Quality

Parameter	Geometric Mean
BOD5 (g/m ³)	18
Suspended solids (g/m ³)	22
Dissolved reactive phosphorus (g/m ³)	2.4
Total Nitrogen (g/m ³)	10.1
Nitrate Nitrogen (g/m ³)	0.4
Nitrite Nitrogen (g/m ³)	0.1
Ammonia-Nitrogen (g/m ³)	0.7 (summer) 3.0 (winter)
E.coli (cfu/100 mL)	485 (summer) 651 (winter)

Note: Geometric means are provided to enable consistency with historical monitoring and trend reporting

Effluent quality shall be monitored in accordance with the resource consent conditions contained in Appendix A.

5 Design Basis

5.2 Soil Types

In determining the irrigation depths to be applied, the operators need to have regard to the different soil types at the land treatment site. Generally the 91 ha site (between Makoura Stream and the river berm) consists of generally free draining soils are silty-textured (silt loam and silty clay loam textures) with intermittent clay-rich layers at depth.

On the river berm area the alluvium is coarser, with a tendency to have sandy textures sometimes interspersed with gravels plus fine sandy loams, sandy loams and gravelly sand textures as well as some loamy silts. These soils are free draining.

On the 107 ha site to the west of Makoura Stream, the soils are generally finer textured than those on the 91 ha site and the clay-enriched layers tend to be at shallower depth nearer the centre of the property. These clay rich soils are poorly to imperfectly drained.

Refer to the Table 5.1 for appropriate irrigation rates for the different soil types.

5.3 Irrigation Rates

The irrigation depth discharged to the border strips is expected to be around 70-100 mm every 7-10 days or up to 150 mm during dry conditions. Treated effluent application should be, as far as practicable, uniform over the available area for even nitrogen and phosphorus loading.

Generally, the irrigation depths will be controlled to provide an average application of effluent plus rainfall, as set out in Table 5.1.

Table 5.1

Irrigation Depths and Areas for Soil Types

Soil type	Area (ha)	Summer Average/Max (mm/day)	Winter Average/Max (mm/day)
Free draining	71	10/15	5/5
Clay rich	26	10/10	0/5
Total	97		

Note: The application rate is the total liquid applied i.e. effluent plus rainfall. Irrigation areas include the decommissioned pond area (22 ha)

Rainfall and soil moisture will be monitored daily and the operator will make a decision on the actual depth of effluent to be applied. An automatic rain gauge will be used to stop the irrigation pumps in the event of significant rainfall that will result in an effluent/rainfall depth greater than an average application of 10 mm/day.

5.4 Seasonal Discharge Pattern

Table 5.2 provides a monthly summary of the average daily volume and occurrences of discharges to land and the river based on an average year's weather, influent wastewater and river flow data (noting that there could be a simultaneous discharge to the river and to land).

Table 5.2

Summary of Average Daily Discharge

Month	Daily average influent flow [m ³ /d]	Discharge to river	% of inflow to river	Discharge to Land	% of inflow to land	% of days with no river discharge	% days to land	% days to river	Average daily river flow [m ³ /d]
January	13,228	4,333	33	7,747	59	80	93	20	11.1
February	13,104	4,860	37	7,596	58	81	93	19	14.7
March	13,050	5,828	45	7,228	55	77	95	23	11.3
April	12,397	5,041	41	6,635	54	77	98	23	12.1
May	13,131	12,259	93	2,990	23	28	84	72	18.3
June	16,106	14,006	87	2,868	18	2	83	98	32.9
July	20,707	18,741	91	2,698	13	0	79	100	38.0
August	19,964	17,401	87	2,950	15	1	83	99	32.3
September	17,159	14,164	83	3,056	18	6	81	94	26.9
October	19,652	12,730	65	6,607	34	21	85	79	42.0
November	15,626	7,413	47	7,153	46	51	88	49	21.9
December	14,939	7,593	51	7,035	47	51	88	49	17.9

Note: Using data from 1 January 1997 – 3 March 2008

From Table 5.2, the average total annual volume of discharge to land is 1,963,000 m³. Over the 97 ha of irrigation land this represents an average irrigation depth of 2.0 m per year.

6 Border Strip Operation

6.1 Pump Station Operation

Effluent from the final maturation Pond 6 discharges through a 900 mm dia transfer pipe to supply a 900 dia header manifold for the irrigation pumps. The border strips on the decommissioned pond area are fed by gravity with a main directly from the irrigation pumps manifold.

The irrigation pump station includes the pumps, screens, filters, controls and telemetry associated with the border strip irrigation and buffer zone drip systems. The pumps are dry mounted centrifugal sewage pumps with a pump duty of up to 300 l/s at 20 m head (confirm at detailed design) to supply two bubble-up valves simultaneously. Variable speed drive (VSD) controls are required to maintain the flow rate over the varying elevations.

Three pumps supply the border strip irrigation with varied sizes to supply the different irrigation areas. Valves in the discharge manifold allow pumps to be taken out of service with the irrigation area being supplied by another pump. Removal and movement of the irrigation pumps will require the use of the gantry and hoist in the pump station building. The pumps supply three trunk mains to provide reticulation to the 91 and 107 ha sites.

6.2 Application Control

The system is controlled by a series of electrically actuated zone valves and manual border strip bubble-up valves (the 14 zones in the 75 ha site, and 3 zones in the decommissioned pond area are shown on Drg C-624). These valves allow the operator to discharge to each zone and to each border strip.

The border strip treatment system is partially automated. The operator must manually open bubble-up valves in each strip to be used, and can then either manually control the discharge or schedule an automatic discharge sequence for the border strip zones. The automatic discharge sequence will start the irrigation pump and sequentially actuate the zone valves.

When visiting a zone to close/open the bubble up valves, the operator is to check the strips for ponding or signs of pasture stress, and odour emissions.

Effluent application should be managed on a rotational basis to maximise the return between applications. The application times to each border strip should be adjusted to ensure that under and over-watering is minimised. Over or under watering can result in soil and pasture damage and/or excess runoff. The sequence of applications can be set in the automatic control system. The sequence restarts at the beginning after a set time period (adjustable) is completed.

If a valve fails to open, then the next area valve in the sequence is selected and a non-urgent alarm is raised. If a valve fails to close, the pump is stopped and a non-urgent alarm is raised. If a valve is not in automatic mode, then the next zone in the sequence is selected.

Prior to the effluent advance reaching the end of each strip, the automated irrigation system will close the zone valve and open the next zone valve. The programming of the control system for sequencing will require fine-tuning during the start-up period due to the variability between each zone of soil type, strip length and slope.

The duration and area of discharge should be recorded on effluent irrigation worksheets if the cycling is being done manually, otherwise the discharge details will be logged electronically in the control system. The flow to the border strip discharge area will be monitored by the flow meter on the delivery line to the pumps.

The border strip irrigation pumps will deliver 100 to 150 l/s from each bubble-up valve. Border strips that are 24 m wide will have two bubble-up valves with a total flow in the range of 200 to 300 l/s. Opening only one valve will decrease the loading. This will need to be determined during commissioning and adjusted for changing conditions.

6.3 Run-off Control

Some experience will be needed to determine the time of application required to allow the effluent to just reach the end of the border strip, and no further. These times can be adjusted by the operator seasonally if required. In the event that effluent reaches the end of the border strip, it will be discharged to the wipe-off drain for collection. Wipe-off drains will be connected to irregular shaped areas at the end of border strips which will be formed into infiltration areas. These will be excavated through to the permeable subsoils to promote the run-off infiltration to groundwater. The areas are shown on Drgs C603 & C604. This will reduce runoff pumped back to the ponds or stormwater discharges to the Makoura Stream.

The wipe-off drains will be used to collect rainfall run-off from the border-strips. If the enhanced infiltration capacity is exceeded in the wipe-off drains, the runoff from the first two hours of rainfall will go to the recycle pump station and be returned to the ponds. This period (called the first flush) allows for contaminants to be returned to the ponds for later irrigation or river discharge. Following the first flush, 'clean' stormwater will be suitable for discharge to Makoura Stream.

The wipe-off drain along the Makoura Stream will run back to a recycle pump station adjacent to Pond 6 (as indicated on Drawing C602). Wipe off drains on the river berm will extend into the layer of sandy gravels which are very permeable so any excess run-off will percolate directly into the subsoils.

The operator shall monitor the wipe-off drains routinely to determine if there is excessive run-off of effluent into the drain. Excessive run-off will require the pump operation time for that particular zone to be altered through the irrigation control system.

The operator shall routinely check the wipe-off drains for excessive weed growth which may restrict the passage of effluent and storm-water. Weeds should be removed and disposed of.

The infiltration areas will require maintaining by the operator to remove silt from run-off that accumulates and reduces the infiltration rate. Silt should be disposed at the Nursery Road clean-fill. Ripping the infiltration area and/or addition of coarse sand may be used to restore the permeability. The areas should also be kept free of excessive weeds.

6.4 Border Strip Management and Maintenance

The operational philosophy for irrigating the border strips will be to maximise the volume of wastewater discharged to land, whilst minimising the amount of runoff. Given the variability of soil characteristics and environmental conditions, this philosophy will require the operator to exercise judgement and make adjustment to the automatic control where necessary.

The border strip area requires active management to manage the nutrient loading and maintain the border strip structure and pasture. The following management practices should be adopted:

- Maintain land available for the discharge of treated effluent at all times, except when pasture renewal is required.
- Maintain levees between borders in good condition to prevent spillage of effluent between borders.

- The border strip area is planted in pasture for baleage or silage production. The pasture should be a species that will actively grow and absorb nutrients during winter months. The recommended species is a perennial rye grass mix and with white and/or red clover. The pasture dry matter yield is likely to be in the range of 12,000-16,000 kg/ha/yr.
- Pasture renewal shall be limited to no more than 20% of the area at any one time. It is expected that pastures will need to be re-grassed every four to six years, using direct drilling to avoid cultivation.
- Pasture should be sown and maintained in good condition and be free of weeds.
- It is important to maintain an active sward of grass when treated effluent is applied.
- Harvesting of the pasture should occur whenever there is a yield of approximately 3,000 kg dry matter per hectare with harvesting generally confined to the months of September to May. Prior to harvesting, the pasture will be spelled (no irrigation) for as long as possible and for a period of at least ten days with no treated wastewater being applied. Low impact, wide wheels on machines will also help reduce soil compaction. It will be important to avoid having heavy harvesting equipment on the land at times of wet soil conditions.
- A schedule shall be kept of the zone number, date of cut, harvest details and tests carried out.
- Pasture should be regularly harvested (four to five times per year) and removed from the site to ensure that nitrogen uptake is maximised and minimal nitrogen recycling can occur. Table 6.1 shows an estimated nitrogen balance for the border strip area using "cut and carry" system.
- Pasture needs to be monitored, including regular nutrient budgeting. The aim will be to keep fertilising to a minimum to reduce the leaching of nutrients to groundwater. It is expected that clover will assist N deficiencies. However, if pasture growth becomes impacted by nutrient deficient soil, then fertilising will be undertaken to remediate.
- With a cut-and-carry system it is likely that potassium will become deficient and hence will need to be applied regularly to the land
- Regular monitoring of the soil/plant system is important so that potential problems can be identified and addressed before they become significant issues; such monitoring should also include the preparation of a regular nutrient budget.
- Inherent in a cut-and-carry wastewater irrigation operation is the need to exclude grazing animals, although limited use of small grazing animals (for example, sheep) will be beneficial at certain times of the year to 'tidy up' those areas unable to be harvested. Cattle will be excluded from the wastewater irrigated areas, because of the pugging they will cause which will reduce infiltration rates.

Table 6.1
Nitrogen Balance for Border Strip Area

Irrigation – Season ²	Nitrogen (g/m ³)	ADF to Land (m ³ /d)	Annual N to Land (kg/season)	Area (ha)	N Loading (kg/ha/ season) ²	N removed in harvest (kg/ha/ harvest)
Summer	11	7,243	14,500	97	150	350
Winter	11	3,543	7,100	71	100	

Notes:

1) Assumes pasture yield is 14,000 kg dry matter per hectare/per annum and pasture contains 2.5% N

2) Assumes a season is 183 days.

6.5 Use of the Balage or Silage

Fonterra's 2007 revised policy on human sewage application to dairy farms, only permits very high quality treated wastewater (i.e., treated with filtration and UV disinfection) being spread onto pasture fed to dairy cows. The proposed quality of the effluent from the upgraded oxidation ponds therefore will exclude the silage or baleage being fed to dairy cows. However, it has been confirmed that there will be a demand in the area locally by dry stock farmers for the harvested silage or baleage.

For the cut and carry system, it will be necessary to demonstrate that the baleage or silage is suitable to feed to cattle, without the need for a stand down period.

The baleage shall be tested for stock food value and suitability for stock feed. Tests shall include yeasts and moulds and listeria. Bales containing Listeria shall be stored separately and disposed of for composting or mulch and not sold for feed.

6.6 Buffer Zones

Buffer areas along the north and west boundaries of the proposed irrigation area and bounding the east side of Makoura Stream, will be established as part of the upgrade. These buffer strips will provide an appropriate setback distance from waterways and adjacent properties that is free of border strip irrigation and other MWTP operations. The planted buffers will be 10m wide and will be planted in a range of tree species, compatible with proposals for enhancing the ecological and recreational potential of the stream.

The boundary buffers will be planted to screen the site, where agreed with residents to the south, west and north of the site.

Drip irrigation of treated effluent will be used to establish and maintain the buffer planting and other areas where irrigation is needed. Drip irrigation to buffer areas, shall only occur when soil moisture drops below levels required for satisfactory growth. This will be initiated manually by the operator.

6.7 Power Failure

The WWTP inlet works and inlet pump station has a backup generator in the event of a power failure. Irrigation pumps will not be provided with a backup power supply as effluent can be stored in the oxidation ponds or discharged to the Ruamahanga River in accordance with the discharge rules. In the unlikely event of a power failure occurring when the storage was full, emergency discharge provisions would apply.

6.8 Preventive Maintenance

All equipment shall be routinely inspected and maintained in accordance with the suppliers recommendations. Equipment and checks should include the following;

- Irrigation pump and pump flow rate
- Automated butterfly valves for zone control
- Bubble-up valves
- Flow meters
- Weather recording instruments
- Plant PLC

7 Health and Safety

The Masterton District Council is bound by the Health and Safety in Employment Act 1992 to provide a safe work environment. In addition to the guidelines in this Plan, the MDC Health and Safety requirements for operations staff shall be adhered to.

Operations staff are required to wear protection appropriate for use in working with wastewater. The following precautions are recommended while working around wastewater;

- Hands and fingers should be kept away from the nose, mouth eyes and ears
- Hands and forearms up to the elbow should be washed thoroughly with disinfectant soap and hot water before eating or smoking, and after work
- Fingernails should be kept short and foreign materials should be removed from the nails with a stiff soapy brush
- Avoid smoking when handling wastewater or when in any wastewater facility
- Door knobs and other building fixtures should not be contaminant by dirty hands or gloves
- Work clothes worn in wastewater areas should be thoroughly cleaned before being put away
- Street clothes and clean clothes should be stored in a locker separate from used work clothes
- All cuts and scratches should be treated with antiseptic and covered immediately
- A shower should be taken as soon as practical after each work day.

Protective clothing should be worn appropriate to the nature of the work and the environment including the following;

- Surgical or rubber gloves should be worn when performing tasks involving direct contact with wastewater or sludge
- Hard hats - where there is potential for head injury
- Protective footwear - to protect from crushing
- Gumboots - to protect from contaminated soil, wastewater or effluent
- High visibility clothing – in areas of moving machinery or harvesting equipment
- Flotation jackets – over water
- Ear protection – in noisy environments
- Gauze type masks – in high aerosol areas
- Safety glasses or goggles – to protect from eye injury
- Harness and lifelines – to assist to safety those affected by a hazard
- Radio or mobile phone – for emergency call
- Gas meter – to monitor the atmosphere of an area
- Explosion proof torch – for use in hazards areas with poor natural light.

It is noted that the border-strip irrigation method was selected to avoid potential for aerosols in drift from spray irrigators.

Operators having regular contact with raw wastewater or treated effluent, should be immunised against Hepatitis A and B, Tetanus and Polio.

Hazards may be present due to poisonous gases, explosive gases or lack of oxygen which are particular risks at wastewater pump stations. Appropriate procedures must be followed and appropriate equipment worn when working in areas with hazardous gases.

8 Resource Consent Monitoring

The following shall be monitored in accordance with the WWTP resource consent;

8.1 Discharge quality

Refer to Appendix A for the consent conditions for the monitoring of the discharge quality.

8.2 Groundwater levels and quality

Groundwater bores will be monitored for level on a monthly basis.

Groundwater bores shall be sampled three monthly for the first year of operation of the scheme. Following the first year and after satisfactory review, the monitoring frequency would be decreased to six monthly. Refer to Appendix A for the sampling parameters and the bore monitoring sites.

8.3 Discharge to Air

It is not expected that odours will be created by the border-strip irrigation system unless the soils become saturated for periods long enough to form anoxic or anaerobic conditions. The operator will record areas of ponding or odour emissions from the soil.

8.4 Soil and pasture analysis.

Refer to Appendix A for the consent conditions for soil monitoring.

In addition the following soil and pasture analysis shall be carried out;

8.4.1 Soil Structure

i. Penetrometer readings across the site

Take 20 measurements across a 50m transect across the site. Mean values and compare with non-irrigated sites, and to pre-irrigation measurements. Take measurements once per year in early spring.

ii. Soil Infiltration Measurements [Clothier and White 1981]

Measure in Spring and Autumn, six reps across the site. These measurements should indicate any deterioration in topsoil infiltration.

Method

A metal tube is 'carved' into the soil to give an 'undisturbed column'. A Perspex infiltrometer is placed on top of the soil column and the time for the water level to drop a given distance is recorded. The soil infiltration rate can be calculated and compared with non irrigated sites and with pre-irrigation measurements.

iii. Soil chemical testing, quick tests [pH, calcium, phosphorous, potassium, magnesium and salt]. Test on four to five areas, once per annum.

8.4.2 Health of Pastures

i. Pasture Quadrant Cuts

Method

A metal Quadrant of known areas [0.25m^2] is placed on the ground and the pasture inside the quadrant is cut to ground level with electric shears. All the cut herbage is collected and placed in a plastic bag to prevent moisture loss.

Send samples to a laboratory for analysis. Dry matter determinations on individual samples, full chemical analysis on bulked samples. Use DM and P or N analysis to determine uptake and removal of nutrient from the area. Calculate and record harvest yields [e.g. bales of hay or tonnes of silage per ha]

8.4.3 Nitrogen Loading

TKN and Nitrate – N shall be measured to assess the loading of nitrogen on the treatment system. AgResearch shall carry out a nutrient budget each autumn using a model for assessment.

8.4.4 Pasture Consultants Report

A farm consultant visually assesses pastures and a six monthly report is obtained for pasture management. A strategy of crop management is carried out for:

- Fertiliser additions
- Insect attack
- Pasture diseases
- Pasture composition.

Appendices

Appendix A - Monitoring for Resource Consent Conditions

[Consent Conditions to be included following the resource consent being granted].
